Guiding Land Conservation for Biodiversity in Massachusetts

Introduction

In this report, the Natural Heritage & Endangered Species Program provides you with site-specific biodiversity information for your area. Protecting our biodiversity today will help ensure the full variety of species and natural communities that comprise our native flora and fauna will persist for generatons to come.

The information in this report is the result of two statewide biodiversity conservation planning projects, BioMap and Living Waters. The goal of the BioMap project, completed in 2001, was to identify and delineate the most important areas for the long-term viability of terrestrial, wetland, and estuarine elements of biodiversity in Massachusetts. The goal of the Living Waters project, completed in 2003, was to identify and delineate the rivers, streams, lakes, and ponds that are important for freshwater biodiversity in the Commonwealth. These two conservation plans are based on documented observations of rare species, natural communities, and exemplary habitats.

What is a Core Habitat?

Both BioMap and Living Waters delineate Core *Habitats* that identify the most critical sites for biodiversity conservation across the state. Core Habitats represent habitat for the state's most viable rare plant and animal populations and include exemplary natural communities and aquatic habitats. Core Habitats represent a wide diversity of rare species and natural communities (see Table 1), and these areas are also thought to contain virtually all of the other described species in Massachusetts. Statewide, BioMap Core Habitats encompass 1,380,000 acres of uplands and wetlands, and Living Waters identifies 429 Core Habitats in rivers, streams, lakes, and ponds.

Get your copy of the BioMap and Living Waters reports! Contact Natural Heritage at 508-792-7270, Ext. 200 or email natural.heritage@state.ma.us. Posters and detailed technical reports are also available.

Core Habitats and Land Conservation

One of the most effective ways to protect biodiversity for future generations is to protect Core Habitats from adverse human impacts through land conservation. For Living Waters Core Habitats, protection efforts should focus on the *riparian areas*, the areas of land adjacent to water bodies. A naturally vegetated buffer that extends 330 feet (100 meters) from the water's edge helps to maintain cooler water temperature and to maintain the nutrients, energy, and natural flow of water needed by freshwater species.

In Support of Core Habitats

To further ensure the protection of Core Habitats and Massachusetts' biodiversity in the long-term, the BioMap and Living Waters projects identify two additional areas that help support Core Habitats.

In BioMap, areas shown as Supporting Natural *Landscape* provide buffers around the Core Habitats, connectivity between Core Habitats, sufficient space for ecosystems to function, and contiguous undeveloped habitat for common species. Supporting Natural Landscape was

Massachusetts Division of Fisheries and Wildlife

BioMap and Living Waters:

Guiding Land Conservation for Biodiversity in Massachusetts

D:- M---

generated using a Geographic Information Systems (GIS) model, and its exact boundaries are less important than the general areas that it identifies. Supporting Natural Landscape represents potential land protection priorities once Core Habitat protection has been addressed.

In Living Waters, *Critical Supporting Watersheds* highlight the immediate portion of the watershed that sustains, or possibly degrades, each freshwater Core Habitat. These areas were also identified using a GIS model. Critical Supporting Watersheds represent developed and undeveloped lands, and can be quite large. Critical Supporting Watersheds can be helpful in land-use planning, and while they are not shown on these maps, they can be viewed in the Living Waters report or downloaded from www.mass.gov/mgis.

Understanding Core Habitat Species, Community, and Habitat Lists

What's in the List?

Included in this report is a list of the species, natural communities, and/or aquatic habitats for each Core Habitat in your city or town. The lists are organized by Core Habitat number.

For the larger Core Habitats that span more than one town, the species and community lists refer to the <u>entire</u> Core Habitat, not just the portion that falls within your city or town. For a list of <u>all</u> the state-listed rare species within your city or town's boundary, whether or not they are in Core Habitat, please see the town rare species lists available at <u>www.nhesp.org</u>.

The list of species and communities within a Core Habitat contains <u>only</u> the species and

Table 1. The number of rare species and types of natural communities explicitly included in the BioMap and Living Waters conservation plans, relative to the total number of native species statewide.

Vascular Plants	23	114
Fishes	11	57
Mussels	7	12
Aquatic Invertebrates	23	An estimated > 2500

natural communities that were explicitly included in a given BioMap or Living Waters Core Habitat. Other rare species or examples of other natural communities may fall within the Core Habitat, but for various reasons are not included in the list. For instance, there are a few rare species that are omitted from the list or summary because of their particular sensitivity to the threat of collection. Likewise, the content of many very small Core Habitats are not described in this report or list, often because they contain a single location of a rare plant

Massachusetts Division of Fisheries and Wildlife

BioMap and Living Waters:

Guiding Land Conservation for Biodiversity in Massachusetts

species. Some Core Habitats were created for suites of common species, such as forest birds, which are particularly threatened by habitat fragmentation. In these cases, the individual common species are not listed.

What does 'Status' mean?

The Division of Fisheries and Wildlife determines a status category for each rare species listed under the Massachusetts Endangered Species Act, M.G.L. c.131A, and its implementing regulations, 321 CMR 10.00. Rare species are categorized as Endangered, Threatened, or of Special Concern according to the following:

- Endangered species are in danger of extinction throughout all or a significant portion of their range or are in danger of extirpation from Massachusetts.
- *Threatened* species are likely to become Endangered in Massachusetts in the foreseeable future throughout all or a significant portion of their range.
- *Special Concern* species have suffered a decline that could threaten the species if allowed to continue unchecked or occur in such small numbers or with such restricted distribution or specialized habitat requirements that they could easily become Threatened in Massachusetts.

In addition, the Natural Heritage & Endangered Species Program maintains an unofficial watch list of plants that are tracked due to potential conservation interest or concern, but are not regulated under the Massachusetts Endangered Species Act or other laws or regulations. Likewise, described natural communities are not regulated any laws or regulations, but they can help to identify ecologically important areas that are worthy of protection. The status of natural

Legal Protection of Biodiversity

BioMap and Living Waters present a powerful vision of what Massachusetts would look like with full protection of the land that supports most of our biodiversity. To create this vision, some populations of state-listed rare species were deemed more likely to survive over the long-term than others.

Regardless of their potential viability, all sites of state-listed species have full legal protection under the Massachusetts Endangered Species Act (M.G.L. c.131A) and its implementing regulations (321 CMR 10.00). Habitat of state-listed wildlife is also protected under the Wetlands Protection Act Regulations (310 CMR 10.37 and 10.59). The *Massachusetts Natural Heritage Atlas* shows Priority Habitats, which are used for regulation under the Massachusetts Endangered Species Act and Massachusetts Environmental Policy Act (M.G.L. c.30) and Estimated Habitats, which are used for regulation of rare wildlife habitat under the Wetlands Protection Act. For more information on rare species regulations, see the *Massachusetts Natural Heritage Atlas*, available from the Natural Heritage & Endangered Species Program in book and CD formats.

BioMap and Living Waters are conservation planning tools and do not, in any way, supplant the Estimated and Priority Habitat Maps which have regulatory significance. Unless and until the combined BioMap and Living Waters vision is fully realized, we must continue to protect all populations of our state-listed species and their habitats through environmental regulation.

communities reflects the documented number and acreages of each community type in the state:

- Critically Imperiled communities typically have 5 or fewer documented sites or have very few remaining acres in the state.
- *Imperiled* communities typically have 6-20 sites or few remaining acres in the state.
- *Vulnerable* communities typically have 21-100 sites or limited acreage across the state.
- **Secure** communities typically have over 100 sites or abundant acreage across the state; however excellent examples are identified as Core Habitat to ensure continued protection.

Massachusetts Division of Fisheries and Wildlife

Understanding Core Habitat Summaries

Following the BioMap and Living Waters Core Habitat species and community lists, there is a descriptive summary of each Core Habitat that occurs in your city or town. This summary highlights some of the outstanding characteristics of each Core Habitat, and will help you learn more about your city or town's biodiversity. You can find out more information about many of these species and natural communities by looking at specific *fact sheets* at www.nhesp.org.

Next Steps

BioMap and Living Waters were created in part to help cities and towns prioritize their land protection efforts. While there are many reasons to conserve land – drinking water protection, recreation, agriculture, aesthetics, and others – BioMap and Living Waters Core Habitats are especially helpful to municipalities seeking to protect the rare species, natural communities, and overall biodiversity within their boundaries. Please use this report and map along with the rare species and community fact sheets to appreciate and understand the biological treasures in your city or town.

Protecting Larger Core Habitats

Core Habitats vary considerably in size. For example, the average BioMap Core Habitat is 800 acres, but Core Habitats can range from less than 10 acres to greater than 100,000 acres. These larger areas reflect the amount of land needed by some animal species for breeding, feeding, nesting, overwintering, and long-term survival. Protecting areas of this size can be

very challenging, and requires developing partnerships with neighboring towns.

Prioritizing the protection of certain areas within larger Core Habitats can be accomplished through further consultation with Natural Heritage Program biologists, and through additional field research to identify the most important areas of the Core Habitat.

Additional Information

If you have any questions about this report, or if you need help protecting land for biodiversity in your community, the Natural Heritage & Endangered Species Program staff looks forward to working with you.

Hadley

Core Habitat BM659

This Core Habitat supports the largest known concentration of Eastern Spadefoot toads in the Connecticut River Valley. It also contains an unusual type of natural community, the Black Gum-Pin Oak-White Oak "Perched" Swamp, that is found only in this region of Massachusetts.

Natural Communities

This Core Habitat contains a high-quality, moderate-sized Black Gum-Pin Oak-Swamp White Oak "Perched" Swamp that is surrounded by both forested upland and agricultural fields. Black Gum-Pin Oak-Swamp White Oak "Perched" Swamps are an unusual type of wetland found in Massachusetts in one area of the Connecticut River Valley. This community type is dominated by Red Maple, with Black Gum, Pin Oak, and Swamp White Oak.

Vertebrates

This Core Habitat encompasses a complex of low-lying agricultural fields and patches of deciduous forest in Hadley and Sunderland that collectively support the largest known concentration of Eastern Spadefoot toads in the Connecticut River Valley. The toads occur in areas with sandy soils and breed in seasonally flooded pools, including depressions in agricultural fields. This Core Habitat also includes habitat along small streams, including Russellville, Mohawk, and Dry Brooks. The area is criss-crossed with roads and conservation planning efforts are needed here, as these habitats are already partially fragmented and are gradually being lost to residential development.

Core Habitat BM709

This Core Habitat, located along the Connecticut River in Hadley and Hatfield, provides important river and rivershore habitats for rare plants and animals, including Bald Eagles, Midland Clubtail dragonflies, and the Sandbar Willow.

Plants

Sandy beaches and river sandbars in this Core Habitat support rare rivershore species such as Frank's Lovegrass, a Species of Special Concern, and Sandbar Willow, Threatened in Massachusetts.

Invertebrates

This Core Habitat includes a stretch of the Connecticut River between Hatfield and Hadley that is habitat for the Endangered Midland Clubtail dragonfly, a species that requires large, sand-bottomed rivers and is not known to occur anywhere in Massachusetts but along the Connecticut River. Virtually all the Midland Clubtail's habitat here appears to be unprotected; pollution and hydrologic alterations originating upstream, downstream, or within this Core Habitat are major threats.

Vertebrates

This Core Habitat encompasses nearly four miles of partially forested shoreline along both sides of the Connecticut River in Hatfield and Hadley. These shorelines and the river itself provide perching and foraging habitat for wintering and non-breeding Bald Eagles.

Massachusetts Division of Fisheries and Wildlife

Hadley

Core Habitat BM714

Natural Communities

This Core Habitat contains a Black Gum-Pin Oak-Swamp White Oak "Perched" Swamp of moderate quality. These swamps are an unusual type of wetland found in Massachusetts in one area of the Connecticut River Valley. The community type is dominated by Red Maple, with Black Gum, Pin Oak, and Swamp White Oak. Here the swamp is poorly buffered due to its residential and agricultural setting, but it maintains the species diversity and structure that are characteristic of this rare natural community.

Core Habitat BM740

This Core Habitat is an important area for several rare plants and animals. It encompasses riparian habitats along portions of the Connecticut River, the Fort River, and Hop Brook, including extensive forested wetlands and small wet meadows in Lawrence Swamp. These areas support a diversity of rare dragonflies and plants, as well as Wood Turtles, Spotted Turtles, Four-toed Salamanders, and Bald Eagles. The Core Habitat also contains unusual wetland communities, including one that is specific to this part of the state. While some parts of this Core Habitat are protected, many riparian habitats appear to be unprotected.

Natural Communities

This Core Habitat contains large examples of both Major-River Floodplain Forest and Black Gum-Pin Oak-Swamp White Oak "Perched" Swamp natural communities. Major-River Floodplain Forests are dominated by Silver Maple. This community type is found along the floodplains of large rivers. The soils are enriched with nutrients brought by annual floods, resulting in a diversity of plants and insects. This floodplain forest is well-developed, with only a few exotic invasive plant species restricted to small sections where disturbances such as trails exist. This is the second-best known Major-River Floodplain Forest included on the BioMap. Meanwhile, Black Gum-Pin Oak-Swamp White Oak "Perched" Swamps are an unusual type of wetland found in Massachusetts in one area of the Connecticut River Valley. This community type is dominated by Red Maple, with Black Gum, Pin Oak, and Swamp White Oak.

Plants

Nine rare plant populations are found growing in different parts of this large Core Habitat. Several populations of the Climbing Fern, a plant Species of Special Concern, are found in swampy areas, while one population of the Threatened Green Dragon grows along a river floodplain. Other rare plant species found here are the Narrow-Leaved Spring Beauty (Endangered) and the Sandbar Willow (Threatened).

Hadley

Invertebrates

In its westernmost portion, this Core Habitat includes a 5-km stretch of the Connecticut River and surrounding uplands in Northampton and Hadley that are critical habitat for rare dragonfly species, including the Endangered Riverine Clubtail dragonfly, the Threatened Arrow Clubtail dragonfly, and the Brook Snaketail dragonfly, a Species of Special Concern. Some portions of the shoreline habitat are within the protected areas such as the Rainbow Beach and Sheperds Island Conservation Areas and the Connecticut River Greenway and Skinner State Park. Pollution and hydrologic alterations originating upstream, downstream, or within this Core Habitat are major threats to the rare species inhabiting the area.

Vertebrates

The diverse riparian and wetland habitats within this Core Habitat support significant populations of Wood Turtles, Spotted Turtles, and Four-toed Salamanders. Wood Turtles may use over 13 connected miles of the Fort River and Hop Brook and associated wetlands, and range out 600 yards into forested and agricultural uplands. Lawrence Swamp is a large complex of forested and shrub wetlands, small wet meadows, and vernal pools that supports a significant population of Spotted Turtles. Four-toed Salamanders occur in pools and seeps where sphagnum moss is abundant. Conservation efforts should seek to maximize the width and extent of undeveloped riparian corridors along the Fort River and Hop Brook to ensure that the habitat quality of this Core Habitat does not get further degraded by roads and suburban development.

This Core Habitat also encompasses partially wooded shorelines and islands along a portion of the Connecticut River in Northampton. These areas provide relatively undisturbed perching habitat for wintering and non-breeding Bald Eagles that forage along the river, as well possible future nest sites for this species.

Core Habitat BM785

This Core Habitat comprises the western half of the Holyoke Range in Hadley and South Hadley, from Rte. 116 west toward the Connecticut River. This mainly roadless area, located in the rapidly developing Connecticut River Valley, provides important habitat for several species of state-protected rare amphibians and reptiles. It also contains oak woodlands that support the Threatened Orange Sallow moth, a variety of habitats that support several rare plant species, and a range of natural communities, from rocky summits to Black Ash Swamps. Half of the Core Habitat is protected as conservation land, and further protection of large and important areas is needed.

Natural Communities

This Core Habitat contains the excellent, bald-like, rocky summits on Bare Mountain and Mount Hitchcock in the Holyoke Range. It also contains a species-rich Circumneutral Talus Forest associated with one of the few known locations of a state Endangered plant species. Further down slope are some pockets of Black Ash Swamp, which is a variant of Red Maple Swamp with Black Ash co-dominant in the canopy. The soils that support Black Ash Swamps are enriched with less acidic, more nutrient-rich groundwater seepage.

Hadley

Plants

A cluster of rare plant occurrences is found within this Core Habitat, including Red Mulberry (Endangered), Linear-Leaved Milkweed (Threatened), and Purple Clematis (Species of Special Concern).

Invertebrates

This Core Habitat includes the open oak woodlands on the rocky summits and ridges of the Holyoke Range that are habitat for the Threatened Orange Sallow moth. This large area of habitat is undeveloped, unfragmented, and located in close proximity to other Core Habitat for the Orange Sallow moth within the Mount Tom State Reservation to the southwest. Although various tracts within this Core Habitat are protected land, including the Holyoke Range State Park, Skinner State Park, and municipal conservation land, conservation of remaining areas of unprotected land within this Core Habitat is desirable to increase the amount of contiguous protected habitat and to help ensure the long-term viability of the Orange Sallow moth and other rare species inhabiting the area.

Vertebrates

This Core Habitat is characterized by steep, rocky hillsides of deciduous and White Pine forests, with scattered seasonal pools, small brooks, seeps, and forested wetlands in valleys and on hillside terraces. It supports significant populations of Marbled, Four-toed, and Jefferson Salamanders, as well as Eastern Box Turtles. Because it includes a large roadless area, it likely represents one of the best remaining opportunities to preserve viable populations of these species in the Connecticut River Valley. Over two miles of Elmer Brook run along the base of the south slope of the Holyoke Range and provide habitat for Wood Turtles, although this species may have been impacted by road mortality along Pearl Street and Rte. 116. This Core Habitat also provides a large block of breeding and migration habitat within the Connecticut River Valley for a number of species of forest birds.

Hadley

Core Habitat BM789

This Core Habitat encompasses riparian areas along the Manhan River and several of its tributaries. It includes fields, wet meadows, shallow marshes, shrub and forested wetlands, and a large oxbow along the west side of the Connecticut River. This diverse area contains habitats for three species of state-protected rare turtles, as well as Bald Eagles. It supports rare insects like the Endangered Zebra Clubtail dragonfly, and rare plants such as the Endangered Many-Fruited False-Loosestrife. The Core Habitat encompasses several floodplain forest communities, including an unusually high-quality Small-River Floodplain Forest. Parts of this Core Habitat are already protected as conservation land, including MassAudubon's Arcadia Wildlife Sanctuary, and further protection of key areas is needed.

Natural Communities

This Core Habitat contains a diversity of Floodplain Forest communities of varied quality. The Small-River Floodplain Forest within this Core Habitat is one of only three high-quality known locations of this community type in the state. Small-River Floodplain Forests are Silver Maple-Green Ash forests occurring on alluvial soils of small rivers and streams. This rare type of forest is often heavily impacted by hydrology alterations and is usually associated with a suite of invasive exotic species; however, this occurrence has remained in excellent condition and is disturbance free. The Transitional Floodplain and High-Terrace Floodplain Forests here are also important occurrences of these uncommon community types, especially because of their proximity to each other.

Plants

Two populations of the very rare Many-Fruited False-Loosestrife grow on exposed mud and depressions within floodplains along the Connecticut River. The Threatened Green Dragon, a relative of Jack-in-the-Pulpit, is also growing in floodplain habitat along the Connecticut.

Invertebrates

The Manhan River and its tributaries within this Core Habitat provide important habitat for rare dragonflies including the Endangered Zebra Clubtail and the Brook Snaketail. In addition, wet meadows and shrub swamps with Elderberry located at various points along this stretch of the Manhan River provide habitat for the Elderberry Longhorned Beetle. Portions of the Manhan River flow through extensive areas of developed and agricultural land, which threatens the river and its rare species inhabitants with hydrologic alteration and pollution.

Hadley

Vertebrates

The extensive, connected areas of habitat that border the Manhan River and its tributaries provide significant habitat for Wood Turtles. Documented observations indicate that Spotted Turtles and Eastern Box Turtles are present here as well. A number of nearby roads, including Rte. 10, have likely adversely affected populations of these turtles through road mortality. This Core Habitat should be a priority for conservation planning for Wood Turtles.

The section of the Connecticut River and its forested shorelines within this Core Habitat provide relatively undisturbed foraging and perching habitat for wintering and non-breeding Bald Eagles. Protection and management of wet meadows and shallow marshes near the west side of the Connecticut River can benefit a variety of birds, including rails, bitterns, and certain species of waterfowl and shorebirds. Managed grasslands at Arcadia Sanctuary provide habitat for grassland birds. The diverse habitats within this Core Habitat provide important migration habitat for a number of bird species.

Hadley

Core Habitat LW354

This middle section of the Connecticut River flows through a mix of developed, agricultural, and forested lands, and is bounded by the Holyoke dam to the south, and the Tuners Falls dam to the north. The river provides unparalleled freshwater habitats for fishes and invertebrates in Massachusetts.

The river is of conservation significance because it supports the only known occurrence of the Endangered Yellow Lampmussel in Massachusetts. This freshwater mussel lives in large rivers, and was recently rediscovered in the mainstem of the Connecticut River at depths of up to fifteen feet. In the past, the Connecticut River was known to support eleven mussel species, and today there are nine species known from the river.

The Bachelor Brook tributary in Granby and South Hadley also supports a very diverse assemblage of freshwater mussels, including eight of the twelve species found in Massachusetts. Four of these species are state-listed as rare: the Endangered Brook Floater, the Triangle Floater, the Eastern Pondmussel, and the Creeper mussel. These species have generally been found in moderate to slow flowing stretches of the brook below rocky riffles in either mixed sand and gravel runs or in sandy pools. The Brook Floater in particular is believed to be sensitive to low oxygen, pollution, and silt, and is known from only five water bodies in the state. There is some evidence that this small Brook Floater population is reproducing, making this a particularly important site.

Stony Brook in South Hadley supports five freshwater mussel species, including the rare Creeper mussel. This species is found scattered along the lower reach of Stony Brook, near the confluence with the Connecticut River, as it flows slowly over loose sands, gravels, and clays. There are only nineteen Core Habitats for the Creeper, which represent the water bodies that support the most robust populations of this rare mussel across the state.

From Holyoke northward, the Connecticut River mainstem is also home to ten species of state-listed dragonflies, the majority of which are found only in large rivers. The tributaries of the Connecticut River are important habitat for the state-listed dragonflies found in smaller rivers. The Connecticut River and the Connecticut River Valley provide a northward corridor for more southerly species, thus contributing a unique fauna to Massachusetts.

In addition to invertebrate habitats, the Connecticut River supports a diversity of fish habitats. The stretch of the Connecticut River in Montague is an important spawning (breeding) area for the state- and federally-Endangered Shortnose Sturgeon. This long-lived, prehistoric-looking fish is particularly susceptible to habitat degradation and mortality because it does not reach maturity until it is at least 5 - 10 years old. The Shortnose Sturgeon moves many miles during its life cycle, using other parts of the Connecticut River at different times of the year. The stretch of the river from Montague and Deerfield down to Hatfield and Hadley is important feeding and overwintering habitat.

In Hatfield, Hadley, and Northampton, a portion of the Connecticut River and its associated tributaries were delineated as Core Habitat for the Eastern Silvery Minnow, a fish Species of Special Concern. This species is only known from the Connecticut River and lower Deerfield

Massachusetts Division of Fisheries and Wildlife

Living Waters: Core Habitat Summaries

Hadley

River in Massachusetts. It spawns in backwaters, laying eggs directly on the river bottom in areas where the emergent vegetation provides cover. Siltation, pollution, and water level changes threaten this species.

The stretch of the Connecticut River in Gill, Greenfield, and Montague downstream from the Turners Falls Dam is presumed habitat for Burbot, a fish Species of Special Concern. Burbot also likely inhabits the Connecticut River in the vicinity of the Fort River confluence in Hadley. This enigmatic fish, a freshwater member of the cod family, has been found at only a few locations in Massachusetts. Not much is known about its life history in the state, although it may live mostly in deep pools of the Connecticut River.

Shallow areas in the Connecticut River north of the Sunderland bridge support a population of the diminutive American Waterwort, an Endangered aquatic plant. This area also supports the uncommon Water Star-Grass, a plant with tiny yellow flowers and long grass-like leaves. Native freshwater plants like these species are an important component of aquatic ecosystems. They provide habitat and nutrition for fish and invertebrates, and they add oxygen to the water through photosynthesis. Permanent protection of the riparian land adjacent to this Core Habitat, and careful management of runoff from developed and agricultural areas will help ensure the continued quality of this key Core Habitat in Massachusetts.

Core Habitat LW426

The Fort River, as it flows from Amherst into Hadley to join the Connecticut River, is a key freshwater habitat for fishes, freshwater mussels, and aquatic insects.

The predominantly sandy riverbed and the combination of riffles and pools along the Fort River provide important habitats for a diverse group of freshwater mussels, with seven of the state's twelve species found here. Several specimens of the federally and state-Endangered Dwarf Wedgemussel were recently rediscovered in the river. The Triangle Floater occurs in good numbers and is distributed throughout the river, whereas the Eastern Pondmussel is found less frequently in sandy pools or quieter waters. The uncommon Eastern Pearlshell is abundant and very well-distributed throughout the river, and is an indicator of cool, clean rivers that support its trout fish hosts. While some mussel populations are abundant here, many of the state-listed rare species appear to be declining. Permanent protection of the undeveloped riparian areas adjacent to this Core Habitat and the control of sediment inputs from roads and agricultural areas are first steps toward protecting this valuable freshwater habitat.

This Core Habitat also provides habitat for rare dragonflies. These aquatic insects are good indicators of ecosystem health, confirming that these freshwater habitats are important for other aquatic species as well. For example, a section of the Fort River in Hadley supports one of six known populations of Bridle Shiner in the Connecticut Watershed. This fish Species of Special Concern has a small range from southern New England to South Carolina, and has been declining or extirpated in much of the region. The Bridle Shiner is typically found in well-vegetated, quiet waters. It feeds on small aquatic insects and other invertebrates, and is an important part of the freshwater ecosystem as prey for larger fishes.

The lower reaches of the Fort River and into the Connecticut River are presumed habitat for

Living Waters: Core Habitat Summaries

Hadley

Burbot, another fish Species of Special Concern. Burbot is a freshwater member of the cod family, and has been found at only a few locations in Massachusetts. Not much is known about its life history in the state, as this species remains an enigma to biologists.
